Cheat Sheet: Python Data Structures Part-2

Dictionaries

```
Package/Method Description
                                                                  Code Example
                 A dictionary
                 is a built-in
                 data type that Example:
                 represents a
                                   1. 1
                 collection of
                                  2. 2
Creating a
                 key-value
Dictionary
                                   1. dict_name = {} #Creates an empty dictionary
                  pairs.
                                   2. person = { "name": "John", "age": 30, "city": "New York"}
                 Dictionaries
                 are enclosed
                                 Copied!
                 in curly
                 braces {}.
                                Syntax:
                                   1. 1
                                   1. Value = dict_name["key_name"]
                  You can
                 access the
                                 Copied!
                  values in a
Accessing Values dictionary
                                Example:
                  using their
                 corresponding
                                   1. 1
                                   2. 2
                  keys.
                                  1. name = person["name"]
                                   2. age = person["age"]
                                 Copied!
                                Syntax:
                                   1. 1
                 Inserts a new
                 key-value
                                   1. dict_name[key] = value
                 pair into the
                 dictionary. If
                                 Copied!
                  the key
Add or modify
                 already exists, Example:
                 the value will
                                   1. 1
                 be updated;
                                  2. 2
                 otherwise, a
                 new entry is

    person["Country"] = "USA" # A new entry will be created.

                 created.
                                   2. person["city"] = "Chicago" # Update the existing value for the same key
                                 Copied!
del
                 Removes the Syntax:
                 specified key-
                 value pair
                 from the
                                   1. del dict_name[key]
                 dictionary.
                 Raises a
                                 Copied!
                  KeyError if
                  the key does
                                Example:
                  not exist.
                                   1. del person["Country"]
```

about:blank 1/5

11/3/23, 4:46 PM about:blank

```
Copied!
                                Syntax:
                  The update()
                                   1. 1
                  method
                  merges the
                                   1. dict_name.update({key: value})
                  provided
                                  Copied!
                  dictionary
update()
                  into the
                                Example:
                  existing
                  dictionary,
                                   1. 1
                  adding or
                  updating key-
                                   1. person.update({"Profession": "Doctor"})
                  value pairs.
                                  Copied!
                  The clear()
                                Syntax:
                  method
                  empties the
                                   1. 1
                  dictionary,
                                   1. dict_name.clear()
                  removing all
                  key-value
                                  Copied!
                  pairs within
clear()
                  it. After this
                                Example:
                  operation, the
                  dictionary is
                                   1. 1
                  still
                                   1. grades.clear()
                  accessible
                  and can be
                                  Copied!
                  used further.
                                Example:
                  You can
                  check for the
                                   1. 1
                  existence of a
                                   2. 2
key existence
                  key in a
                                   1. if "name" in person:
                  dictionary
                                           print("Name exists in the dictionary.")
                  using the in
                  keyword
                                 Copied!
                  Creates a
                                Syntax:
                  shallow copy
                                   1. 1
                  of the
                  dictionary.
                                   1. new_dict = dict_name.copy()
                  The new
                  dictionary
                                  Copied!
                  contains the
                  same key-
copy()
                                Example:
                  value pairs as
                  the original,
                                   1. 1
                                   2. 2
                  but they
                  remain
                                   1. new_person = person.copy()
                  distinct
                                   new_person = dict(person) # another way to create a copy of dictionary
                  objects in
                                 Copied!
                  memory.
                  Retrieves all
keys()
                                Syntax:
                  keys from the
                                   1. 1
                  dictionary
                  and converts
                                   1. keys_list = list(dict_name.keys())
                  them into a
                  list. Useful
                                  Copied!
                  for iterating
                  or processing Example:
                  keys using
                  list methods.
                                   1. 1
```

about:blank 2/5

11/3/23, 4:46 PM about:blank

```
1. person_keys = list(person.keys())
                                 Copied!
                                Syntax:
                  Extracts all
                                   1. 1
                  values from
                                   1. values_list = list(dict_name.values())
                  the dictionary
                  and converts
                                 Copied!
                  them into a
values()
                  list. This list
                                Example:
                  can be used
                  for further
                                   1. 1
                  processing or
                                   1. person_values = list(person.values())
                  analysis.
                                 Copied!
                                Syntax:
                  Retrieves all
                                   1. 1
                  key-value
                  pairs as tuples
                                   1. items_list = list(dict_name.items())
                  and converts
                  them into a
                                 Copied!
items()
                  list of tuples.
                                Example:
                  Each tuple
                  consists of a
                                   1. 1
                  key and its
                  corresponding
                                   1. info = list(person.items())
                  value.
                                 Copied!
```

Sets

Package/Method	Description	Code Example
_	_	Syntax:
		1. 1
add()	Elements can be added to a set using the 'add()' method. Duplicates are automatically removed, as sets only store unique values.	<pre>1. set_name.add(element)</pre>
		Copied!
		Example:
		1. 1
		 fruits.add("mango")
		Copied!
		Syntax:
		1. 1
clear()	The 'clear()' method removes all elements from the set, resulting in an empty set. It updates the set in-place.	<pre>1. set_name.clear()</pre>
		Copied!
		Example:
		1. 1
		<pre>1. fruits.clear()</pre>
		Copied!
copy()	The 'copy()' method creates a shallow copy of the set. Any modifications to the	Syntax:

about:blank 3/5

Defining Sets

discard()

about:blank

copy won't affect the original set.

A set is an unordered collection of

set operations.

unique elements. Sets are enclosed in curly braces `{}`. They are useful for

storing distinct values and performing

1. 1

```
1. new_set = set_name.copy()
```

Copied!

Example:

- 1. 1
- 1. new fruits = fruits.copy()

Copied!

Example:

- - 1. 1
- 1. empty_set = set() #Creating an Empty
- 2. Set fruits = {"apple", "banana", "orange"}

Copied!

Syntax:

- 1. 1
- 1. set_name.discard(element)

Use the 'discard()' method to remove a specific element from the set. Ignores if the element is not found.

Copied!

Example:

- 1. 1
- 1. fruits.discard("apple")

Copied!

Syntax:

- 1. 1
- 1. is_subset = set1.issubset(set2)

Copied!

current set is a subset of another set. It returns True if all elements of the current set are present in the other set, otherwise False.

The 'issubset()' method checks if the

Example:

- 1. 1
- 1. is_subset = fruits.issubset(colors)

Copied!

Syntax:

is superset = set1.issuperset(set2)

issuperset()

issubset()

The 'issuperset()' method checks if the current set is a superset of another set. It Example: returns True if all elements of the other set are present in the current set, otherwise False.

1. 1

1. is_superset = colors.issuperset(fruits)

Copied!

pop()

The 'pop()' method removes and returns Syntax: an arbitrary element from the set. It raises a 'KeyError' if the set is empty. Use this method to remove elements when the order doesn't matter.

1. removed_element = set_name.pop()

Copied!

about:blank

11/3/23, 4:46 PM

about:blank

Example:

1. 1

1. removed_fruit = fruits.pop()

Copied!

Syntax:

1. 1

1. set_name.remove(element)

Use the 'remove()' method to remove a remove() specific element from the set. Raises a 'KeyError' if the element is not found.

Copied!

Example:

1. 1

1. fruits.remove("banana")

Copied!

Syntax:

1. 1

2
 3

1 1

1. union_set = set1.union(set2)

2. intersection_set = set1.intersection(set2)

3. difference_set = set1.difference(set2)

4. sym_diff_set = set1.symmetric_difference(set2)

Set Operations

Perform various operations on sets: `union`, `intersection`, `difference`, `symmetric difference`.

Copied!

Example:

1. 1

2. 2 3. 3

4. 4

1. combined = fruits.union(colors)

2. common = fruits.intersection(colors)

3. unique_to_fruits = fruits.difference(colors)

4. sym_diff = fruits.symmetric_difference(colors)

Copied!

Syntax:

1. 1

1. set_name.update(iterable)

update()

The 'update()' method adds elements from another iterable into the set. It maintains the uniqueness of elements.

Copied!

Example:

1. 1

1. fruits.update(["kiwi", "grape"])

Copied!
